Time Series Forecasting

Dr. Anand Jayaraman
ajayaraman@gmail.com

Mar 5, 2017

Thanks to Dr.Sridhar Pappu for the material

I thought you guys were supposed to be working on your sales projections for Q3.

That's exactly what we're doing.

© 2012 LeadFormix Inc.

"Prediction is very difficult, especially if it's about the future."

--Niels Bohr, Nobel laureate in Physics

What is Time Series data?

- A sequence of data points in successive order, indexed by time.

$$y_t, y_{t-1}, y_{t-2}, y_{t-3}, y_{t-4}, \dots$$

- Eg: Population of the country listed year-wise,
Temperature in the city listed by the hour,
Number of iPhones sold listed for each quarter

Forecasting

- Factors needed to forecast the next month's stock price of Tata Motors (\hat{y}_{t+1})
 - Current price (y_t)
 - Current Sales, Revenue and profit data (x_1)
 - Sales trend (x_2)
 - Level debt carried by the company (x_3)
 - Competition (x_4)
 - Import/export rules (x_5)
 - Interest rate environment (x_6)
 - US/INR exchange rate (x_7)
 - Tax rates (x_8)
 - Crack down on black money? (x_9)
 - Cost of steel? (x_{10})
 - Number of smart phones sold? (x_{11})

Forecasting

$$\hat{y}_{t+1} = g(t, x_1, x_2, x_3 \dots, y_t, y_{t-1}, y_{t-2}, \dots)$$

g might be some complex linear or nonlinear function.

Time series forecasting attempts to do same forecast just using the past data of y , without relying on any other external predictors (x_i).

Typical Time Series

$$\hat{y}_{t+1} = f(t, y_t, y_{t-1}, y_{t-2} \dots)$$

f can be linear or nonlinear function

Why Time Series forecasting?

- Causal independent variables are
 - Unknown to us
 - Not available
 - Might not fit the data well
 - Difficult to forecast

NASDAQ: CTSH - 26-Feb 4:00 PM GMT-5

57.04 USD ↓0.20 (0.35%)

2026

MY HOBBY: EXTRAPOLATING

FORECASTING THROUGH TREND ANALYSIS

Regression with time

$$\hat{y}_{t+1} = f(t)$$

Regression on Time

- Use when trend is the most pronounced
- ACF decays exponentially and PACF has very few spikes

Seasonality

Regression Analysis – Linear fit

Quadratic Trend

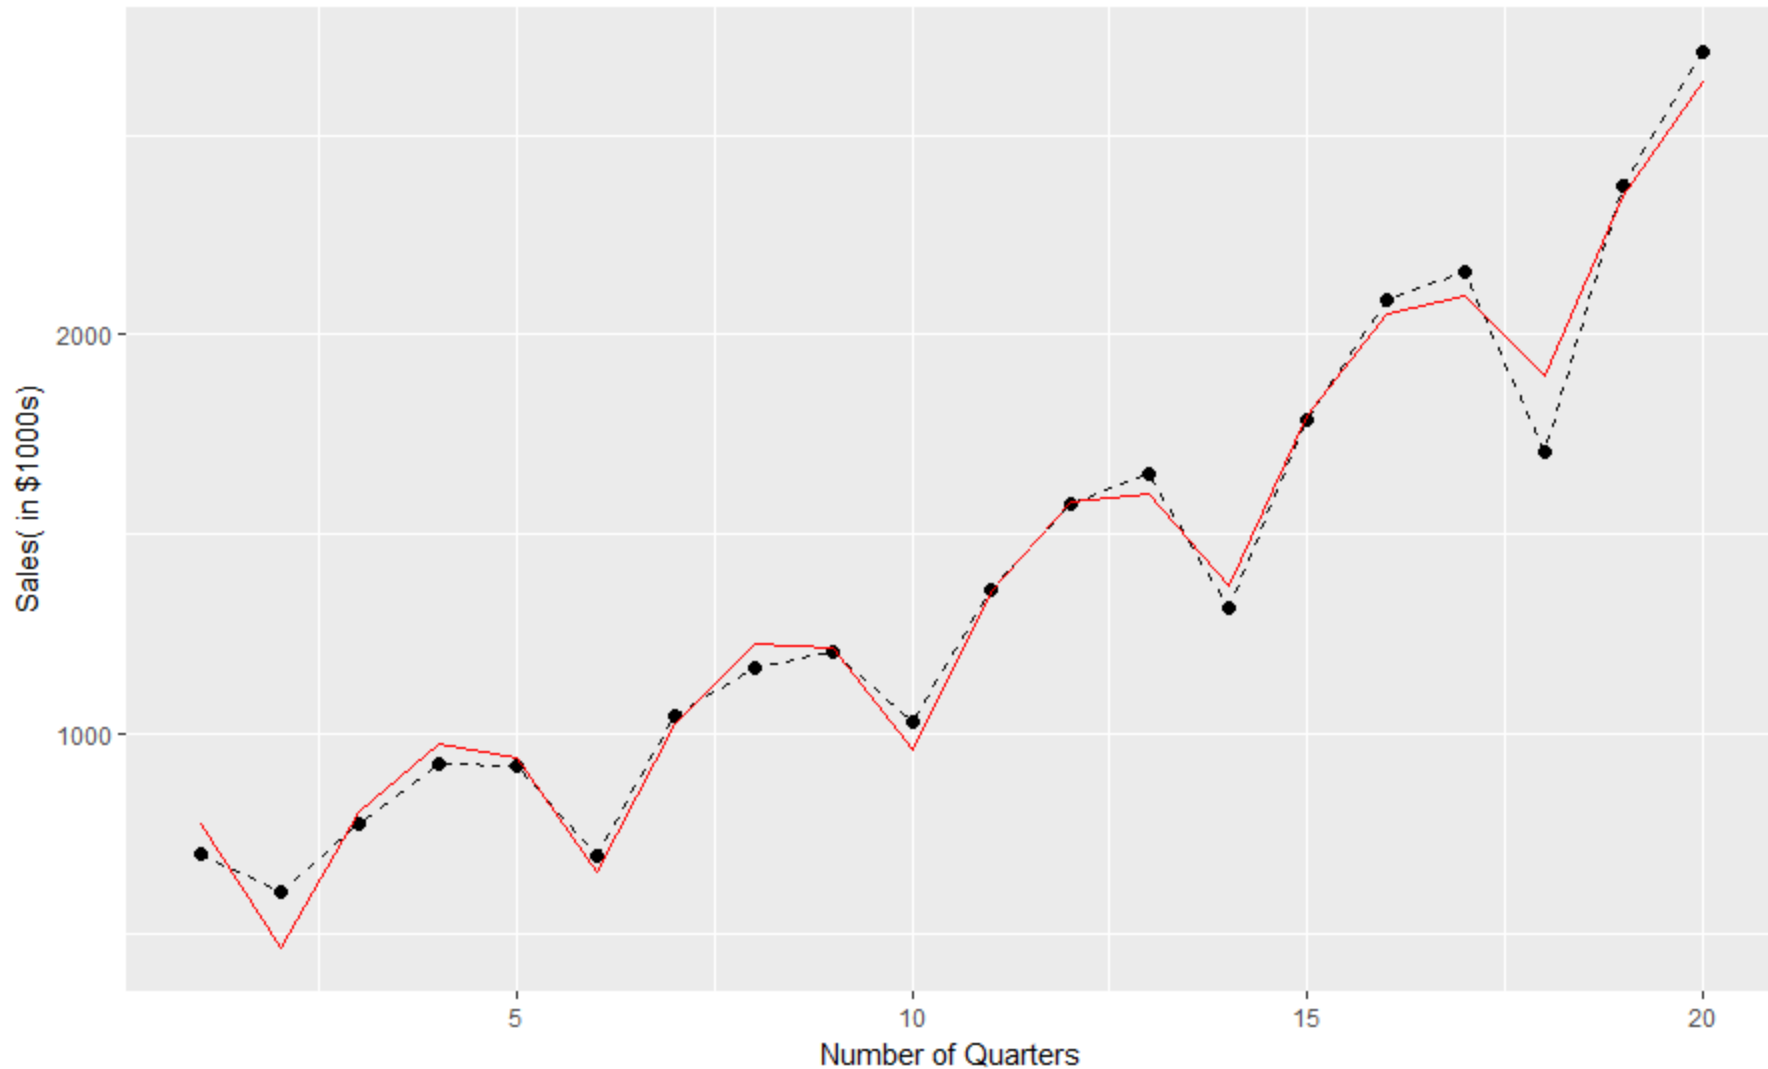

Seasonal Regression Models

Quarter	Value of		
	X_{3t}	X_{4t}	X_{5t}
1	1	0	0
2	0	1	0
3	0	0	1
4	0	0	0

$$Y_t = \beta_0 + \beta_1 X_{1t} + \beta_2 X_{2t} + \beta_3 X_{3t} + \beta_4 X_{4t} + \beta_5 X_{5t} + \varepsilon_t$$

where, $X_{1t} = t$ and $X_{2t} = t^2$.

Seasonal Regression Models

Quadratic fit with seasonality

Plotting the fitted data-points separately for each quarter, shows how R manages to do such a good fit. Its basically fitting a quadratic line for each quarter with a different intercept.

Seasonal Regression Models

Seasonal Regression Models - Births

Another Crude Way of Incorporating Seasonality

- Take the trend prediction and actual prediction.
- Depending on additive or multiplicative model compute the deviation and map it as seasonality effect for each prediction.
- Take averages of the seasonality value. Use this to make future predictions.

Case

Year	Quarter	Time variable (this is created)	Revenues (in \$M)
2008	I	1	10.2
	II	2	12.4
	III	3	14.8
	IV	4	15
2009	I	5	11.2
	II	6	14.3
	III	7	18.4
	IV	8	18

```

$$y = 10.0393 + 0.9440x$$

Seasonality: Multiplicative

Time	Observed values TSI* (assuming no impact of cyclical)	Predicted values (per the regression) T*	SI* = TSI/T
1	10.2	10.983	0.929
2	12.4	11.927	1.040
3	14.8	12.871	1.150
4	15.0	13.815	1.086
5	11.2	14.759	0.759
6	14.3	15.703	0.911
7	18.4	16.647	1.105
8	18.0	17.591	1.023

* T: Trend; S: Seasonal; I: Irregular

Quarterly Seasonality

Time	Average seasonality factor
Q1	$0.844 \left(= \frac{0.929+0.759}{2} \right)$
Q2	0.975
Q3	1.127
Q4	1.054

Time	Observed values TSI* (assuming no impact of cyclicity)	Predicted values (per the regression)	SI* = TSI/T
1	10.2	10.983	0.929
2	12.4	11.927	1.040
3	14.8	12.871	1.150
4	15.0	13.815	1.086
5	11.2	14.759	0.759
6	14.3	15.703	0.911
7	18.4	16.647	1.105
8	18.0	17.591	1.023

Computations

- Trend $Y_9 = 10.039 + 0.944(9) = 18.535$
- Corrected for seasonality and randomness: $18.535 * 0.844 = 15.643$

Births in NY

```
> birthstimeseries <- ts(births,
+ frequency=12,
+ start=c(1946,1))

Additive or Multiplicative

Source: <http://www.forsoc.net/2014/11/11/can-you-identify-additive-and-multiplicative-seasonality/>

Goodness of Fit

- MSE (Mean square error)
- MAE (Mean absolute error)
- RMSE (Root mean square error)
- MAPE (Mean absolute percent error)
- NMSE (Normalized mean square error)
- NMAE (Normalized mean absolute error)
- NMAPE (Normalized mean absolute percent error)

Issues with Regressing on Time

- It is too much of a curve fit for a statistician to sleep well!
- If there is no trend or if seasonality and fluctuations are more important than trend, then the coefficients behave weirdly

TIME SERIES: AUTO REGRESSIVE METHODS

Auto Regressive Methods

$$\hat{y}_{t+1} = f(y_t, y_{t-1}, y_{t-2} \dots)$$

Identifying Techniques for Different Processes

- We use different techniques for different processes
 - Random stationary
 - Seasonal
 - Trend
- First we need to identify them

AUTOCORRELATION AND PARTIAL AUTOCORRELATION

CSE 7202C

Time Series Descriptive Statistics

- In descriptive statistics covered earlier (central tendencies, measures of variability, skewness, kurtosis, distributions, correlations, etc.), the order of observations in the data was of no consequence.
- In time series descriptive statistics, order of observations is of primary importance and so autocorrelations, etc. play a vital role in identifying the models and their characteristics.

Autocorrelation (ACF) and Partial ACF (PACF)

- ACF: n^{th} lag of ACF is the correlation between a day and n days before that.
- PACF: The same as ACF with all intermediate correlations removed. It is the k_{th} coefficient of the ordinary least squares regression.

$$[y_t] = \beta_0 + \sum_{i=1}^k \beta_i [y_{t-i}] \text{ where}$$

$[y_t]$ is the input time series, k is the lag order and β_i is the i_{th} coefficient of the linear multiple regression.

EXCEL ACTIVITY

Autocorrelation (ACF) and Partial ACF (PACF)

Components of Time Series

- **Trend**
- Seasonality
- Random component

Seasonality

Trend, Seasonality and Randomness

ACF and PACF – Idealized Trend, Seasonality and Randomness

CSE 7202c

ACF and PACF – Idealized Trend

ACF and PACF – Idealized Trend

95% CI: $0 \pm \frac{1.96}{\sqrt{n}}$

- ACF is a bar chart of correlation coefficients of the time series and its lags.
- PACF is a plot of the partial correlation coefficients of the time series and its lags.

ACF and PACF – Idealized Seasonality

ACF and PACF – Idealized Seasonality

Series growth

Series growth

ACF and PACF – Idealized Randomness

ACF and PACF – Idealized Randomness

ACF and PACF – Idealized Trend, Seasonality and Randomness

- Ideal Trend: Decreasing ACF and 1 or 2 lags of PACF
- Ideal Seasonality: Cyclical in ACF and a few lags of PACF with some positive and some negative
- Ideal Random: A spike may or may not be present; even if present, magnitude will be small

ACF and PACF (Real-world): Decomposing Time Series into the 3 Components – Revenue Passenger Miles (RPM)

Decomposition of additive time series

ACF and PACF (Real-world): Decomposing Time Series into the 3 Components – RPM

Stationary and Non-Stationary

- Stationary data has constant statistical properties – mean, variance, autocorrelation, etc. – over time
- If the data is stationary, forecasting is easier!
- Differencing to convert non-stationary to stationary

EXCEL ACTIVITY

Removing Trend from Data

ACF and PACF of Stationary and Non-Stationary

Price of GE stock is highly correlated with the previous day's value.

ACF and PACF of Stationary and Non-Stationary

Daily changes in GE stock price are essentially random.

ACF and PACF of Stationary and Non-Stationary

- Non-stationary series have an ACF that remains significant for half a dozen or more lags, rather than quickly declining to zero.
- You must difference such a series until it is stationary before you can identify the process.

Stationary Model: Moving Averages

Stationary Model: Case 1 – Simple Moving Averages

SMA and WMA – Revenue Passenger Miles

> MAPE-SMA 4.093731 > MAPE-WMA 2.729154

Stationary Model: Case 3 – Exponential ~~Weighted~~ ~~Moving Averages~~ or Exponential Smoothing

Averaging over long periods dampens fluctuations, removing not only the noise but also trend and seasonality.

Moving averages over short recent periods maintains trend and seasonality but determining an optimum number for periods is tricky, even when using metrics like MAE. If averaged over too few periods, irregularities continue to remain and if averaged over long periods, dampening again becomes a problem.

Exponential smoothing **retains all older periods** while giving a greater weight to more recent periods (hence not a MOVING average).

Caution: It doesn't make any one method superior for all situations.

Stationary Model: Case 3 – Exponential ~~Weighted~~ ~~Moving Averages~~ or Exponential Smoothing

$$\hat{Y}_{t+1} = \hat{Y}_t + \alpha(Y_t - \hat{Y}_t)$$

Above equation indicates that the predicted value for time period $t+1$ (\hat{Y}_{t+1}) is equal to the predicted value for the previous period (\hat{Y}_t) plus an adjustment for the error made in predicting the previous period's value ($\alpha(Y_t - \hat{Y}_t)$).

The parameter α can assume any value between 0 and 1 ($0 \leq \alpha \leq 1$).

Exponential Smoothing in Other Ways

$\hat{Y}_{t+1} = \hat{Y}_t + \alpha(Y_t - \hat{Y}_t)$ can be rewritten variously as

$$\begin{aligned} &= \alpha Y_t + (1 - \alpha) \hat{Y}_t \\ &= Y_t - (1 - \alpha)(Y_t - \hat{Y}_t) \\ &= \alpha Y_t + \alpha(1 - \alpha)Y_{t-1} + \alpha(1 - \alpha)^2 Y_{t-2} + \cdots + \alpha(1 - \alpha)^n Y_{t-n} + \cdots \end{aligned}$$

Exponential Smoothing

$$\hat{Y}_{t+1} = \hat{Y}_t + \alpha(Y_t - \hat{Y}_t) \quad \alpha = \frac{2}{N+1}$$

- Forecasting at time t+1 requires both the forecasted value and the True Value at time t
- So if you want to forecast more than 1 time period into the future, the best you can do is to use the last available value
- All future predictions are same! This is in accordance with **stationary** assumption.

ADDING TREND AND SEASONALITY TO MOVING AVERAGE PROCESSES

Holt-Winters Method

- This method separates the forecast into 3 components – Base Level + Trend + Seasonal
- It updates each of the level using a Exponential smoothing with a different smoothing factor.
- The algorithm computes the best possible smoothing factors based on the given data and does subsequent predictions using fitted smoothing constants.

Holt-Winters Method

Additive Seasonality

$$\hat{Y}_t = E_{t-1} + T_{t-1} + S_{t-p}$$

$$\hat{Y}_{t+n} = E_t + nT_t + S_{t+n-p}$$

Multiplicative Seasonality

$$\hat{Y}_t = (E_{t-1} + T_{t-1})S_{t-p}$$

$$\hat{Y}_{t+n} = (E_t + nT_t)S_{t+n-p}$$

The 3 smoothing equations are:

$$E_t = \alpha(Y_t - S_{t-p}) + (1 - \alpha)(E_{t-1} + T_{t-1})$$

$$T_t = \beta(E_t - E_{t-1}) + (1 - \beta)T_{t-1}$$

$$S_t = \gamma(Y_t - E_t) + (1 - \gamma)S_{t-p}$$

$$E_t = \alpha \frac{Y_t}{S_{t-p}} + (1 - \alpha)(E_{t-1} + T_{t-1})$$

$$T_t = \beta(E_t - E_{t-1}) + (1 - \beta)T_{t-1}$$

$$S_t = \gamma \frac{Y_t}{E_t} + (1 - \gamma)S_{t-p}$$

Holt-Winters Method

- 3 components – Trend (T), Seasonality(S) and Base Level/Expectation(E).
- 3 weights – smoothing parameters – are used to update components at each period.
- Initial values for Base Level/Expectation and trend components are obtained using linear regression on time.
- Initial values for seasonal component are obtained from a dummy variable regression using de-trended data.
- In the Expectation equation, the series is seasonally adjusted by subtracting the seasonal component.

AR, MA AND ARIMA MODELS

AR(p) models

- Auto-regressive model of order p

$$\hat{y}_t = \alpha + \beta_1 y_{t-1} + \beta_2 y_{t-2} + \cdots + \beta_p y_{t-p}$$

- We find the best value of parameters $(\beta_1, \beta_2, \dots)$ that minimize the errors in forecast of \hat{y}_t .
- The order of the model p is determined based on the number beyond which PACF terms are zero.

Moving Average or MA(q) models

- Model attempts to predict future values using past error in predictions $\varepsilon_1 = \hat{y}_1 - y_1$
- So MA(2) model is

$$\hat{y}_t = \mu + \phi_1 \varepsilon_{t-1} + \phi_2 \varepsilon_{t-2}$$

Where, μ is the average value of the time series

- Again, the parameters (ϕ_1 , ϕ_2) are determined so that prediction error is minimized.
- The number of terms, q , is determined from the ACF plot. Its the maximum lag beyond which the ACF is 0

ARMA(**p**,q) model

- Combines both AR(p) and MA(q) models

ARIMA(p, d, q) Model

- p is the number of autoregressive terms (a linear regression of the current value of the series against one or more prior values of the series)
 - Maximum lag beyond which PACF is 0
- d is the number of non-seasonal differences (order of the differencing) used to make the time series stationary
- q is the number of past prediction error terms used for the future forecasts.

Model Selection

- The number of parameters (p,d,q) needed to fit, depends on the dataset
- There are techniques that automate model selection
- *auto.Arima* command in R picks the best p,d & q parameters for ARIMA(p,d,q)

Kings Life Expectancy

Source: <http://robjhyndman.com/tsdldata/misc/kings.dat>

Kings Life expectancy: ARIMA forecast

```
> kingsArima <- auto.arima(kingstimeseries)

ARIMA(0,1,1)

Coefficients:
          ma1
      -0.7218
s.e.    0.1208

sigma^2 estimated as 236.2:  log likelihood=-170.06
AIC=344.13  AICc=344.44  BIC=347.56
> # Forecast the life of next 5 kings
> kingsforecast <- forecast.Arima(kingsArima, h=5)
>
> plot.forecast(kingsforecast)
> |
```

Model Identification

- Before Automated functions were available, one used to use ACF plots to determine the best value of (p,d,q) for a given dataset
- Box–Jenkins Methodology: Model identification and model selection
 - Make sure variables are stationary. Difference as necessary to get a constant mean and transformations to get constant variance.
 - Check for seasonality: Decays and spikes at regular intervals in ACF plots.
- Parameter estimation
 - Compute coefficients that best fit the selected model.
- Model checking
 - Check if residuals are independent of each other and constant in mean and variance over time (white noise).

Model Selection

- Check ACF, PACF
- Identify important lag periods
- Create a data frame (table) with these past lag values as independent variables and value to be predicted as dependent variable
- Perform autoregression (AR models)
- To incorporate randomness, use MA

SHAPE	INDICATED MODEL
Exponential, decaying to zero	Autoregressive model. Use the partial autocorrelation plot to identify the order of the autoregressive model.
Alternating positive and negative, decaying to zero	Autoregressive model. Use the partial autocorrelation plot to help identify the order.
One or more spikes, rest are essentially zero	Moving average model, order identified by where plot becomes zero.
Decay, starting after a few lags	Mixed autoregressive and moving average model.
All zero or close to zero	Data is essentially random.
High values at fixed intervals	Include seasonal autoregressive term.
No decay to zero	Series is not stationary.

- Non-seasonal ARIMA models are denoted $\text{ARIMA}(p,d,q)$
- Seasonal ARIMA (SARIMA) models are denoted $\text{ARIMA}(p,d,q)(P,D,Q)_m$, where m refers to the number of periods in each season and (P,D,Q) refer to the autoregressive, differencing and moving average terms of the seasonal part of the ARIMA model.

Birth Timeseries: Stationary?

ARIMA(p,1,q) and ARIMA(p,2,q)

Seasonal ARIMA Model
